I. INTRODUCTION

In a very near future we are going to have the first "full" sky CMB polarization maps. The wealth of information in the CMB polarization field will enable us to determine the cosmological parameters and test and characterize the initial perturbations and inflationary mechanisms with great precision. Cosmological polarized microwave radiation in a simply connected universe is expected to be statistically isotropic. This is a very important feature which allows us to fully describe the field by its power spectrum that can have profound theoretical implications for cosmology. Violation of statistical isotropy (SI) in CMB polarization maps is going to be very important soon. It can now be tested with CMB polarization maps over large sky fraction. Importance of having statistical tests of departures from SI for CMB polarization maps lies not only in interesting theoretical motivations but also in testing cleaned CMB polarization maps for observational artifacts such as residuals from polarized foreground emission. We propose a generalization of the Bipolar Power Spectrum (BiPS) to polarization maps. Application to the observed CMB polarization maps will be soon possible after the release of WMAP three year data. As a demonstration we show that for E-polarization this test can detect breakdown of statistical isotropy due to polarized synchrotron foreground.

II. CMB ANISOTROPY AND POLARIZATION MAPS

CMB anisotropy is completely described by its temperature anisotropy, and polarization. Temperature anisotropy is a scalar random field, $\Delta T(\hat{n}) = T(\hat{n}) - T_0$, on a 2-dimensional surface of a sphere (the sky), where $\hat{n} = (\theta, \phi)$ is a unit vector on the sphere and $T_0 = \int d\Omega T(\hat{n})$ represents the mean temperature of the CMB. It is convenient to expand the temperature anisotropy into spherical harmonics, the orthonormal basis on a 2-dimensional surface of a sphere (the sky), where $\theta, \phi$ are given by

$$\Delta T(\hat{n}) = \sum_{l,m} a_{lm} Y_{lm}(\hat{n}), \quad (1)$$

where the complex quantities, $a_{lm}$ are given by

$$a_{lm} = \int d\Omega Y_{lm}(\hat{n}) \Delta T(\hat{n}). \quad (2)$$

CMB polarization field is described by the Stokes parameters, $Q(\hat{n})$ and $U(\hat{n})$, which depend on the choice of local Cartesian patch the coordinate on the sky. One can combine these Stokes parameters into two complex quantities, $Q(\hat{n}) - i U(\hat{n})$ and $Q(\hat{n}) + i U(\hat{n})$ which transform like spin-2 fields under rotations of the coordinates by an angle $\psi$,

$$(Q(\hat{n}) \pm i U(\hat{n}))(\psi) = e^{\pm 2i\psi}(Q(\hat{n}) \pm i U(\hat{n})). \quad (3)$$
One may thus expand each of them in terms of spin-weighted spherical harmonics, $\pm 2Y_{lm}$,

$$Q(\hat{n}) - i U(\hat{n}) = \sum_{lm} a_{2,lm} Y_{lm}(\hat{n})$$
$$Q(\hat{n}) + i U(\hat{n}) = \sum_{lm} a_{-2,lm} Y_{lm}(\hat{n})$$

Applying spin-lowering (spin-raising) operators $\mathfrak{S}$ ($\mathfrak{D}$) twice on $\pm 2P(\hat{n}) = Q(\hat{n}) \mp i U(\hat{n})$ one can construct two spin-zero fields,

$$\mathfrak{S}_{\hat{n}}^{\pm 2} 2P(\hat{n}) = \sum_{lm} \left[ \frac{(l + 2)!}{(l - 2)!} \right]^{1/2} a_{2,lm} Y_{lm}(\hat{n})$$
$$\mathfrak{D}_{\hat{n}}^{\pm 2} -2P(\hat{n}) = \sum_{lm} \left[ \frac{(l + 2)!}{(l - 2)!} \right]^{1/2} a_{-2,lm} Y_{lm}(\hat{n})$$

For fullsky maps, the above spin-2 fields can be linearly combined to construct two scalar fields $E, B$

$$E(\hat{n}) = \frac{1}{2} \left[ \mathfrak{S}_{\hat{n}}^{\pm 2} 2P(\hat{n}) + \mathfrak{D}_{\hat{n}}^{\pm 2} -2P(\hat{n}) \right]$$
$$B(\hat{n}) = \frac{1}{2i} \left[ \mathfrak{S}_{\hat{n}}^{\pm 2} 2P(\hat{n}) - \mathfrak{D}_{\hat{n}}^{\pm 2} -2P(\hat{n}) \right]$$

Now, expanding these in terms of spherical harmonics,

$$E(\hat{n}) = \sum_{lm} a^{E}_{lm} Y_{lm}(\hat{n})$$
$$B(\hat{n}) = \sum_{lm} a^{B}_{lm} Y_{lm}(\hat{n})$$

we get,

$$a^{E}_{lm} = \frac{1}{2} (a_{2,lm} + a_{-2,lm})$$
$$a^{B}_{lm} = \frac{1}{2i} (a_{2,lm} - a_{-2,lm})$$

Therefore one can characterize CMB anisotropy in the sky maps by three scalar random fields: $T(\hat{n})$, $E(\hat{n})$, and $B(\hat{n})$ with no loss of information. For cut-sky, $E(\hat{n})$ and $B(\hat{n})$ mode decomposition is not unique $\mathfrak{S}$ $\mathfrak{D}$. But since mixing is linear there always exist two linear independent modes. It is possible to formulate the SI of these linear independent modes. Statistical properties of each of these fields can be characterized by $N$-point correlation functions, $(X(\hat{n})X(\hat{n}_2) \cdots X(\hat{n}_n))$. Here the bracket denotes the ensemble average, i.e. an average over all possible configurations of the field, and $X(\hat{n})$ can be any of the $T(\hat{n})$, $E(\hat{n})$, or $B(\hat{n})$ fields. CMB anisotropy is believed to be Gaussian $\mathfrak{S} \mathfrak{D}$. Hence the connected part of $N$-point functions disappears for $N > 2$. Non-zero (even-$N$)-point correlation functions can be expressed in terms of the 2-point correlation function. As a result, a Gaussian distribution is completely described by two-point correlation functions of $X(\hat{n})$,

$$C^{XX'}(\hat{n}, \hat{n}') = \langle X(\hat{n})X'(\hat{n}') \rangle$$

Equivalently, as it is seen from linear relations in eqns. 4 and 6, for a Gaussian CMB anisotropy, $a^X_{lm}$ are Gaussian random variables too. Therefore, the covariance matrix, $\langle a^X_{lm}a^X_{lm'} \rangle$, fully describes the whole field. Throughout this paper we assume Gaussianity to be valid.

### III. STATISTICAL ISOTROPY

Two point correlations of CMB anisotropy, $C^{XX'}(\hat{n}_1, \hat{n}_2)$, are two point functions on $S^2 \times S^2$, and hence can be expanded as

$$C^{XX'}(\hat{n}_1, \hat{n}_2) = \sum_{l_1,l_2,M} A^{XX'}_{l_1,l_2} Y_{l_1l_2}^{TM}(\hat{n}_1, \hat{n}_2).$$

Here $A^{XX'}_{l_1,l_2}$ are coefficients of the expansion (hereafter BipoSH coefficients) and $Y_{l_1l_2}^{TM}(\hat{n}_1, \hat{n}_2)$ are bipolar spherical harmonics defined by eqn. (11). Bipolar spherical harmonics form an orthonormal basis on $S^2 \times S^2$ and transform in the same manner as the spherical harmonic function with $\ell, M$ with respect to rotations $\Pi$. We can inverse-transform $C^{XX'}(\hat{n}_1, \hat{n}_2)$ in eqn. (10) to get the coefficients of expansion, $A^{XX'}_{l_1,l_2}$, by multiplying both sides of eqn. (10) by $Y_{l_1l_2}^{TM}(\hat{n}_1, \hat{n}_2)$ and integrating over all angles. Then the orthonormality of bipolar harmonics, eqn. (12), implies that

$$A^{XX'}_{l_1,l_2} = \int d\Omega_{l_1} \int d\Omega_{l_2} C^{XX'}(\hat{n}_1, \hat{n}_2) Y_{l_1l_2}^{TM}(\hat{n}_1, \hat{n}_2).$$

The above expression and the fact that $C^{XX'}(\hat{n}_1, \hat{n}_2)$ is symmetric under the exchange of $\hat{n}_1$ and $\hat{n}_2$ lead to the following symmetries of $A^{XX'}_{l_1,l_2}$

$$A^{XX'}_{l_1,l_2} = (-1)^{(l_1+l_2-L)} A^{XX'}_{l_2,l_1},$$
$$A^{XX'}_{l_1,l_2} = A^{XX'}_{l_1,l_2} \delta_{l_2k-1}, \quad k = 1, 2, 3, \cdots.$$ 

It has been shown $\mathfrak{S} \mathfrak{D}$ that Bipolar Spherical Harmonic (BipoSH) coefficients, $A^{XX'}_{l_1,l_2}$, are in fact linear combinations of off-diagonal elements of the covariance matrix,

$$A^{XX'}_{l_1,l_2} = \sum_{m_1,m_2} \langle a^X_{l_1m_1}a^X_{l_2m_2} \rangle (-1)^{m_1}c_{l_1m_1,l_2m_2}^{TM}$$

where $c_{l_1m_1,l_2m_2}^{TM}$ are Clebsch-Gordan coefficients. This clearly shows that $A^{XX'}_{l_1,l_2}$ completely represent the information of the covariance matrix. When statistical isotropy holds, it is guaranteed that the covariance matrix is diagonal,

$$\langle a^X_{l_1m_1}a^{X'}_{l_2m_2} \rangle = C^{XX'}_{l_1} \delta_{ll'} \delta_{mm'}$$

and hence the angular power spectra carry all information of the field. Substituting this into eqn. (13) gives

$$A^{XX'}_{l_1,l_2} = (-1)^{l_1}C^{XX'}_{l_1} (2l+1)^{1/2} \delta_{ll'} \delta_{00} \delta_{M0}.$$ 

The above expression tells us that when statistical isotropy holds, all BipoSH coefficients, $A^{XX'}_{l_1,l_2}$, are zero except those with $\ell = 0, M = 0$ which are equal to the
angular power spectra up to a \((-1)^{\ell}(2\ell + 1)^{1/2}\) factor. BipoSH expansion is the most general way of studying two point correlation functions of CMB anisotropy. The well known angular power spectrum, \(C_{\ell}\) is in fact a subset of the corresponding BipoSH coefficients,

\[
C_{\ell}^{XX'} = \frac{(-1)^{\ell}}{\sqrt{2\ell + 1}} A_{00|\ell\ell}' .
\] (16)

Therefore to test a CMB map for statistical isotropy, it is enough to compute the BipoSH coefficients for the maps and check for nonzero BipoSH coefficients. Every statistically significant deviation of BipoSH coefficients from zero would mean violation of statistical isotropy. In the next section we discuss this in more details.

IV. UNBIASED ESTIMATOR

In statistics, an estimator is a function of the known data that is used to estimate an observable quantity. An estimate is the result of the actual application of the function to a particular set of data. Different estimators may be defined for a given observable. The above theory can be used to construct an estimator for measuring BipoSH coefficients from a given CMB map as,

\[
A_{\ell M|\ell' M'}^{XX'} = \sum_{m m'} \sqrt{W_\ell W_{\ell'}} a_{lm}^{XX'} a_{l'm'}^{XX'} c_{lm l'M'}^{\ell M} ,
\] (17)

where \(W_\ell\) is the Legendre transform of the window an isotropic smoothing function that can be applied to the data. The ensemble average of this estimator is given by,

\[
\langle A_{\ell M|\ell' M'}^{XX'} \rangle = \sum_{m m'} \sqrt{W_\ell W_{\ell'}} \langle a_{lm}^{XX'} a_{l'm'}^{XX'} \rangle c_{lm l'M'}^{\ell M} ,
\] (18)

which is its true value. Akin to the well known quadratic estimator \(\hat{C}_\ell = \frac{1}{2\ell + 1} \sum_{m} |a_{lm}|^2\) for \(C_{\ell}\), the above estimator is an unbiased estimator of BipoSH coefficient. However it is impossible to measure all \(A_{\ell M|\ell' M'}^{XX'}\) individually because of cosmic variance. Combining BipoSH coefficients helps to reduce the cosmic variance. Among the several possible combinations of BipoSH coefficients, the Bipolar Power Spectrum (BiPS) has proved to be a useful tool with interesting features. BiPS of CMB anisotropy is defined as a quadratic contraction of the BipoSH coefficients

\[
\kappa_{\ell}^{XX'} = \sum_{l, l', M} |A_{\ell M|l'M'}^{XX'}|^2 \geq 0 .
\] (19)

Non-zero components of BiPS imply break down of statistical isotropy, and this introduces BiPS as a measure of statistical isotropy,

\[
\text{STATISTICAL ISOTROPY } \implies \kappa_{\ell} = 0 \ \forall \ell \neq 0 .
\] (21)

It is important to note that although BiPS is quartic in \(a_{lm}\), it is designed to detect SI violation and not non-Gaussianity \([1, 2, 3, 11, 12]\). An un-biased estimator of BiPS is given by

\[
\tilde{\kappa}_{\ell}^{XX'} = \sum_{l' M} |A_{\ell M|l'M'}^{XX'}|^2 - \mathcal{B}_{\ell}^{XX'} ,
\] (22)

where \(\mathcal{B}_{\ell}^{XX'}\) is the bias related to the SI part of the map and given by the angular power spectrum, \(C_{\ell}\),

\[
\mathcal{B}_{\ell}^{XX'} = \langle \tilde{\kappa}_{\ell}^{XX'} \rangle_{\text{SI}} = (2\ell + 1) \sum_{l_1} \sum_{l_2} W_{l_1} W_{l_2} \times \left[ C_{l_1}^{XX} C_{l_2}^{XX'} + (1)^{\ell} \delta_{l_1 l_2} (C_{l_1}^{XX'})^2 \right] .
\] (23)

The above expression for \(\mathcal{B}_{\ell}^{XX'}\) is obtained by assuming Gaussian statistics of the temperature fluctuations \([1, 11]\). Note, the estimator \(\tilde{\kappa}_{\ell}^{XX'}\) is unbiased, only for SI correlation. In that case, ensemble average of \(\tilde{\kappa}_{\ell}^{XX'}\) is same as its true value which is zero for \(\ell \neq 0\), i.e., \(\langle \tilde{\kappa}_{\ell}^{XX'} \rangle = 0\).

V. EXAMPLE: POLARIZED SYNCHROTRON CONTAMINATION

As an example of how one can detect deviations from statistical isotropy in CMB polarization maps, we make statistically anisotropic polarization maps and estimate the BiPS from them. This can be done in many different ways but here we choose a simple method which results in severe violation of SI and therefore is good for a demonstration of the method. We add polarized synchrotron emission template to the background CMB polarization map. Polarized synchrotron template \((30 \text{ GHz})\) is made using Planck Simulator \([13]\) which uses the model by \([14]\), i.e. the polarization degree is a function of the intensity spectral index while polarization angles are derived from a gaussian distribution. Here we restrict our attention to \(E\) mode polarization only. It is obvious that everything can be done in the same way for \(B\) mode as well. The estimator will then be

\[
A_{\ell M|l'M'}^{EE} = \sum_{m m'} \sqrt{W_\ell W_{\ell'}} a_{lm}^{EE} a_{l'm'}^{EE} c_{lm l'M'}^{\ell M} ,
\] (24)

where \(a_{lm}^{EE}\) are the spherical harmonic transform of the background CMB polarization map plus the polarized synchrotron radiation,

\[
a_{lm}^{EE} = a_{lm}^{E cmb} + a_{lm}^{E sync} .
\] (25)
and $W_l$ is an isotropic filter that allows us to target angular scales of interest by filtering out power on other scales.

We simulate 1000 statistically isotropic CMB polarization maps, add the synchrotron template to each of them, and compute the BiPS for them using the estimators of eqns. (24) and (22). Filters that we use here can be divided into two categories: low pass Gaussian filters

$$W_l^G = N^G \exp \left\{ - \left( \frac{2l+1}{2s+1} \right)^2 \right\}$$

(26)

that cuts power on scales, $l \leq l_s$ and band pass filters of the form

$$W_l^S = 2N^S \left[ 1 - J_0 \left( \frac{2l+1}{2s+1} \right) \right] \exp \left\{ - \left( \frac{2l+1}{2s+1} \right)^2 \right\},$$

(27)

that retains power on scales $l_s \leq l \leq l_t$, where $J_0$ is the spherical bessel function and $N^G$ and $N^S$ are normalization constants chosen such that, $\sum_l \frac{1}{l(l+1)}W_l = 1$, i.e., unit rms for unit flat band angular power spectrum, $l(l+1)C^{XX}_l = 2\pi$.

Results of this computation are shown in Fig. 1 and Fig. 2. We see that CMB polarization maps with no foregrounds are statistically isotropic and have null bipolar power spectrum. Adding polarized synchrotron emission violates statistical isotropy at large angular scales and results in a detectable non-zero BiPS. Retaining only 5% of the polarized synchrotron emission just violates statistical isotropy at the threshold of $1 - \sigma$. At 7.5% of the polarized synchrotron emission clearly shows the violation of statistical isotropy and results in a sharply detectable non-zero bipolar power spectrum at $\kappa_4$.

We should emphasize that this is simply an example to demonstrate how violation of statistical isotropy can be quantified in CMB polarization maps. In reality, we usually expect to deal with cleaned polarized maps which would contain some residuals that have different angular structure. The signal would be much weaker and also have different BiPS characteristics. Hunting tiny residuals from foregrounds in maps of temperature anisotropy using statistical isotropy has been studied \[15\] and similar strategy can be applied to polarization maps when they are available. In addition, other observational artifacts such as anisotropic noise or incomplete (masked) sky can also cause violation of statistical isotropy in a polarization map. In the latter case, the incomplete sky coverage immediately induces a contamination of E-mode of polarization by its B-mode and vice-versa. Then the modified temperature and polarization fields is related to their actual values of full sky coverage by a window matrix $W$, whose elements are basically window functions for temperature and polarization in harmonic space. It can be shown that the estimated BiPS components are in fact linear combinations of that for fullsky CMB maps.
Here bold-faced $\tilde{A}_{LM|l'l''}$ and $A_{LM|l_1l_2}$ are the column matrices corresponding to estimated and true BipoSH coefficients respectively, for the auto and cross-correlations ($TT, TE, TB, ET, EE, EB, BT, BE, BB$) of temperature anisotropy and polarization. The elements of the matrix $N_{LM|l'l''}$ depend on Clebsch-Gordan coefficients and window functions in harmonic space. Hence, the true BipoSH coefficients can be estimated from the pseudo-BipoSH coefficients by inverting the above equation. We defer this to a future publication, a SI analysis of CMB polarization when this effect is important. (The first time. We present a fast and orientation independent test of statistical isotropy using the BiPS signature of the polarized CMB maps is formally encoded by eqn. (28) but its implementation is a challenging task which is currently under progress. (The effects can also be estimated through extensive simulations.)

VI. SUMMARY

We present a novel approach to quantify the violation of statistical isotropy in CMB polarization maps for the first time. We present a fast and orientation independent method which allows for a general test of isotropy using Bipolar Power Spectrum. This method has been previously applied to the temperature anisotropy maps and many various aspects of that are well studied in details. In this paper we extend BiPS to the CMB polarization maps and present a working example to demonstrate its potential.

Acknowledgments

We acknowledge fruitful discussions with Dmitri Pogosyan, Lyman Page, David Spergel and Joe Silk. Our computations were performed on Hercules, the high performance facility of IUCAA. AH acknowledges support from NASA grant LTSA03-0000-0090. Some of the analysis in this paper used the HEALPix package. We acknowledge the use of the Legacy Archive for Microwave Background Data Analysis (LAMBDA). Support for LAMBDA is provided by the NASA Office of Space Science.

APPENDIX A: USEFUL MATHEMATICAL RELATIONS

Bipolar spherical harmonics form an orthonormal basis of $S^2 \times S^2$ and are defined as

$$Y_{\ell M}^{l_1l_2}(\hat{n}_1, \hat{n}_2) = \sum_{m_1m_2} C_{l_1m_1l_2m_2}^{\ell M} Y_{l_1m_1}(\hat{n}_1) Y_{l_2m_2}(\hat{n}_2),$$

(A1)

in which $C_{l_1m_1l_2m_2}^{\ell M}$ are Clebsch-Gordan coefficients. Clebsch-Gordan coefficients are non-zero only if triangularity relation holds, $\{l_1l_2\ell\}$, and $M = m_1 + m_2$. Where the $3j$-symbol $\{abc\}$ is defined by

$$\{abc\} = \begin{cases} 
1 & \text{if } a + b + c \text{ is integer and } |a - b| \leq c \leq (a + b), \\
0 & \text{otherwise},
\end{cases}$$

Orthonormality of bipolar spherical harmonics

$$\int d\Omega_{\hat{n}_1} d\Omega_{\hat{n}_2} Y_{\ell M}^{l_1l_2}(\hat{n}_1, \hat{n}_2) \overline{Y_{\ell'M'}^{l_1'l_2'}(\hat{n}_1, \hat{n}_2)} = \delta_{\ell\ell'} \delta_{l_1l_1'} \delta_{l_2l_2'} \delta_{M'M'},$$

(A2)
